Abstract. Three new for Ukraine species, *Anema tumidulum*, *A. nodulosum*, and *Pyrenocarpon thelostomum* (*Lichinales*, *Lichenaceae*), are reported. They were found in the Dnister Canyon, on the S and W exposed cliff surfaces where water tracks formed 'a black zone' of the *Collematetea cristati* class. Other species forming these communities are *Anema decipiens*, *Psorotrichia schaeereri*, *Peccania coralloides*, *Thallinocarpon nigritellum*, *Thyreia confusa*, and *Verrucaria nigrescens* s. l. The analyzed dataset included three relevés from the Dnister cliff, as well as 14 relevés from literature sources: seven relevés of *Peccania coralloidis-Thyreectum pulvinatae* recorded from Poland, and seven relevés of *Thyreia nigritella-Anema moedlingense* comm. from the Czech Republic. These data were analyzed in JUICE software. All analyzed relevés were separated in two clusters. Three relevés from Dnister Canyon fell into the same cluster with *Thyreia nigritella* – *Anema moelingensis* comm. provided by Wirth in 1972. We consider these communities as a new association *Thallinocarpo nigritelli-Anemum tumidulae*. Diagnostic species of the association are *Thallinocarpon nigritellum*, *Anema tumidulum*, *Staurothele frustulenta*, and *Anema nodulosum*. The lectotype of *Peccania coralloidis-Thyreectum pulvinatae* has been proposed, with diagnostic species *Enchylium polycarpon*, *Leproplaca cirrochroa*, *Placidium rufescens*, *Placynthium nigrum*, *Toninia candida*, and *Synalissa symphorea*. These associations belong to the *Peccanion coralloidis* alliance and differ by their ecological preferences. The association *Peccania coralloidis-Thyreectum pulvinatae* represents the nomenclatural type of the alliance and includes communities on the vertical exposed limestone surfaces in water tracks. The *Thallinocarpo nigritelli-Anemum tumidulae* association occupies similar habitats but in the xeric geolittoral zone along river banks. The alliance *Peccanion coralloidis* and order *Collematetalia cristati* are reported from Ukraine for the first time.

Keywords: cliff, Dnister Canyon, lichen communities, limestone, *Peccanion coralloidis*, syntaxonomy, water tracks

Introduction

The limestone outcrops on the Dnister Canyon (on the Dnister / Dniester River within Ternopil, Khmelnytskyi, Ivano-Frankivsk, and Chernivtsi administrative regions (*oblasts*) in the western part of Ukraine) represent specific communities of vascular plants, bryophytes, lichens, and algae

forming rare tufa habitats (Didukh et al., 2018). In particular, the cliff surface is covered by lichens with cyanobacterial photobionts. It looks like a wide 'black zone' in the upper geolittoral zone. These communities belong to a poorly studied class *Collematetea cristati* (Nowak, 1960; Wirth, 1972; Egea, Llimona, 1984; Bültman et al., 2015). Such communities are very difficult to study because

they consist of species of *Lichinales* that are difficult to identify. Previously, we reported the class *Collematetea cristati* Wirth 1980 in monographs on habitat classification (Kuzemko et al., 2018; Didukh et al., 2020) based on physiognomic observation made only by the first author, since no relevé from Ukraine was available at the time of publication of the monographs. Fortunately, we observed the lichen communities of the *Collematetea cristati* on the Dnister cliffs in 2021. This observation allowed us to provide information on the new records of lichens for Ukraine, as well as their ecological and coenotic peculiarities, in the present article.

Materials and Methods

The data were collected on the Dnister cliffs of the Dnister Canyon at the border between Khmelnytskyi and Chernivtsi administrative regions on 5 June 2021 (Fig. 1A). The lichen communities have been sampled using the Braun-Blanquet approach (Braun-Blanquet, 1932; Khodosovtsev et al., 2011, 2019, 2022). Lichens were identified by standard methods (Smith et al., 2009). Three relevés from the Dnister cliffs were analyzed with JUICE software (Tichý, 2002) together with the 14 relevés from literature: seven relevés of *Peccario coralloides-Thyreum pulvinatae* Nowak 1960 (Nowak, 1960) from Poland and seven relevés of *Thyrea nigritella-Anema moedlingense* comm. (Wirth, 1972) from the Czech Republic. Our analysis was made using PC-Ord v.5 (Grandin, 2006) with the Sørensen (Bray-Curtis) coefficient as a distance measure and flexible beta at -0.25 as the group linkage method. The original Braun-Blanquet scale (Nowak, 1960; Wirth, 1972) was used for Table 1. Nomenclature of lichens mainly follows Kondratyuk et al. (2021). Diagnostic species of the classes and suborder units follows European Vegetation Classification (<https://floraveg.eu/vegetation/>). The lichen specimens are deposited at the Herbarium of the Kherson State University (KHER).

Results

New lichen records for Ukraine

Ten lichen species were registered in three relevés from the Dnister cliffs (Table 1). Three new for Ukraine species of lichens were identified.

Anema nodulosum (Nyl.) Forsell (Fig. 2C).

Thallus disc-form, squamulose, peltate, 2–3(–4) mm in diameter, black, covered by white-bluish pruina; lobes closely adjacent, 0.3–0.5 mm length. Apothecia immersed in squamules, compressed, 0.2–0.4 mm in diameter; disk brown, urceolate to flat, surrounded by black thalline margin, proper margin not visible.

Thallus homoiomerous with loose net of hyphae and cyanobacterial cells in section. Epithecum orange-brown, up to 10 µm high; hymenium hyaline, 70–120 µm wide, I + (bluish);

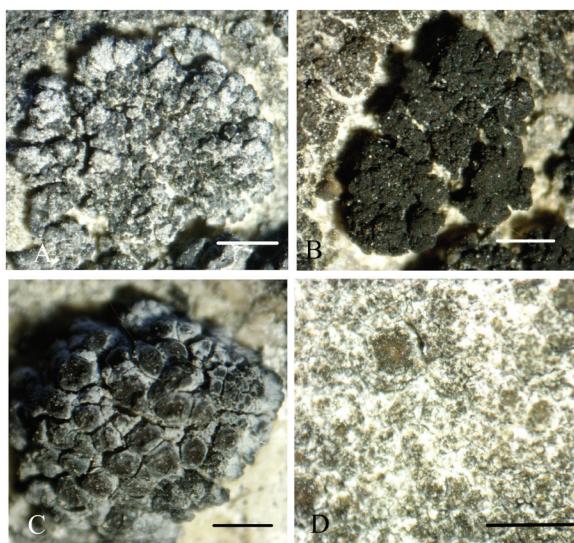

Fig 2. *Anema* and *Pyrenocarpon* species. A: *A. decipiens*; B: *A. tumidulum*; C: *A. nodulosum*; D: *P. thelostomum* (scale: A, C – 0.5 mm; B – 0.7 mm, D – 1.0 mm)

paraphyses simple with slightly swollen apical cells; hypothecium hyaline to yellowish, 100–160 μm thick. Ascii 8-spored, ascospores hyaline, one-celled, 9–15 \times 6–9 μm . Photobiont chroococcoid, 8–15 μm in diam., often in clusters and surrounded by gelatinous hyaline sheath in the centre and yellow-brown in exposed parts.

Specimens examined. Ukraine: Khmelnytskyi Region, Kamianets-Podilskyi District, left bank of the Dnister River, in front of Makarivka village (Chernivtsi Region), cliff above the river, 121 m a.s.l., W exposition, 48.571670 N, 26.753513 E, 05.07.2022, leg. A. Khodosovtsev (KHER15212, 15217).

***Anema tumidulum* Henssen ex P.M. Jørg., M. Schultz & Guttová (Fig. 2B).**

Thallus small, rosette or disc-form, peltate, 3–4 mm in diameter, black, without pruina; lobes small, lobes closely adjacent, 0.3–0.6 mm long; central part covered with small isidia-like outgrowths. Apothecia in Ukrainian specimens not found. In section, thallus is similar to *A. nodulosum*.

Specimens examined. Ukraine: Khmelnytskyi Region, Kamianets-Podilskyi District, left bank

of the Dnister River, in front of Makarivka village (Chernivtsi Region), cliff above river, 121 m a.s.l., W exposition, 48.571670 N, 26.753513 E, 05.07.2022, leg. A. Khodosovtsev (KHER15214, 15215).

***Pyrenocarpon thelostomum* (Ach. ex J. Harriman) Coppins & Aptroot (Fig. 2D).**

Thallus crustose, thin, dark brown to olive-black, cracked-areolate or indistinct. Areoles very small, 0.1–0.2 mm wide, flat, smooth. Apothecia immersed in conical to hemispherical thalline warts, 0.2–0.5 mm across (in section), at first punctiform, then with expanded, brownish disc surrounded by a distinct light brownish proper exciple and olivaceous thalline margin.

Thallus homeomerous, hyphae 3–5 μm wide. Thalline exciple 50–100 μm wide laterally. Proper exciple 25–50 μm wide in upper part. Epithecium yellowish brown. Hymenium colourless, 120–150 μm high, in K/I faintly blue. Paraphyses slender, branched and anastomosing, with slightly swollen apical cells, 3–5 μm wide. Hypothecium colourless. Ascii 8-spored, cylindrical or narrowly clavate, thin-walled, without internal amyloid structures. Ascospores simple, hyaline, ellipsoid, (10–)13–18(–20) \times 5–10 μm . Photobiont cyanobacterial, chroococcoid, cells 5–10 μm wide, enclosed in yellowish to brown-yellowish gelatinous sheaths.

Specimen examined. Ukraine, Khmelnytskyi Region, Kamianets-Podilskyi District, near Yaruga village, cliffs, in fissures, shaded condition, S exposure, 120 m a.s.l., 48.589513 N, 26.723567 E, 05.07.2022, leg. A. Khodosovtsev (KHER15219).

Lichen communities of *Collematetea cristati* Wirth 1980

The black zone of *Collematetea cristati* class on the Dnister cliff has clearly visible continuous line 1–2.5 m wide and 10–20 m long or as dispersed small spots on rain-exposed water tracks (Fig. 1). It starts from 1.0–1.5 m above water level. *Anema decipiens* (A. Massal.) Forssell, *A. nodulosum*, *A. tumidulum*, *Psorotrichia schaeereri* (A. Massal.) Arnold, *Peccania coralloides* (A. Massal.) A. Massal.,

Thallinocarpon nigrillum (Lettau) P.M. Jorg., *Thyreia confusa* Henssen, and *Verrucaria nigrescens* Pers. s. l. occupied S and W exposed cliff surfaces (Table 1, Fig. 1). The dominant species was foliose *Thyreia confusa* (with cover up to 40%). The high cover values were also registered for foliose *Thallinocarpon nigrillum* (up to 10%) and crustose *Psorotischia schaeereri* (up to 10%). *Pyrenocarpon thelostomum* was collected on a shaded rain protected shelf in species-poor communities.

Two clusters were obtained after our analyses of the dataset in JUICE (Table 1). Three relevés from the Dnister cliffs nested in the same cluster with *Thyreia nigrilla-Anema moelingensis* comm. from the Czech Republic. *Thallinocarpon nigrillum*, *Anema tumidulum* and *Anema nodulosum* are common species for the communities recorded both in the Czech Republic and in Ukraine. Two species, *Peccania coralloides* and *Thyreia confusa*, were common in relevés from the Czech Republic, Poland, and Ukraine.

Discussion

Genera *Anema* Nyl. ex Forssell and *Pyrenocarpon* Trevis. in Ukraine

According to the latest prodromus (an annotated checklist) of lichens of Ukraine (Kondratyuk et al., 2021), the genus *Anema* in Ukraine is represented by two species. The first of them, *Anema notarisii* (A. Massal.) Forssell (= *A. nummularium* (Dufour ex Durieu & Mont.) Nyl. ex Forssell), was reported from a few locations in the Autonomous Republic of Crimea (Kopachevskaya, 1986). In its habitus, it is similar to *A. nodulosum* presented here but differs by the absence of pruina on the thallus and by longer central holdfast. The second species, *Anema decipiens* (Fig. 2A), has been reported from Khmelnytskyi Region (Bielczyk et al., 2005). It is similar to *A. tumidulum*, also discussed here, but differs by its bluish pruina on the thallus, more delicate soredia-like granules on the surfaces, and rare presence of apothecia. Thus, at present four species of the genus *Anema* are known in Ukraine,

and three of them we recorded in one relevé on the Dnister cliff.

There are only two species in the genus *Pyrenocarpon*; one of them, *P. montinii* (A. Massal.) Trevis. (= *Psorotichia montinii* (A. Massal.) Forssell) was found on limestone pebbles in Ukraine recently (Khodosovtsev et al., 2018, 2019). The newly recorded species, *P. thelostomum*, differs from *P. montinii* by larger ascospores ($10-22.5 \times 5-12 \mu\text{m}$ vs. $6-13 \times 4-7 \mu\text{m}$ in *P. montinii*), larger ascomata (0.2–0.5 mm vs. 0.1–0.3 mm in *P. montinii*), and, ecologically, by its preference of more or less shaded habitats.

Two associations in *Peccanion coralloides* Moreno et Egea ex Egea in Bültmann et al. 2015

The class *Collematetea cristati* includes few alliances. One of them is *Peccanion coralloides* (*Collematetalia cristati* Wirth 1980) with *Peccanio coralloidis-Thyreetum pulvinatae* Nowak 1960 (Nowak, 1960) as the type association (Bültmann et al., 2015). The association has been described from vertical limestone surfaces on water tracks (Poland). The communities are transitional between *Verrucarietea nigrescentis* Wirth 1980 and *Collematetea cristati*. In our opinion, the most typical to *Peccanio coralloidis-Thyreetum pulvinatae* is relevé 2 described by Nowak (Nowak, 1960: Table 16) because it includes the lowest number of diagnostic taxa from *Verrucarietea nigrescentis*. This relevé does not include *Placynthium nigrum* (Huds.) S.O. Gray, which is diagnostic for *Placynthietum nigrum* (Klement, 1955). We propose this relevé as a lectotype (see below) of the association *Peccanio coralloidis-Thyreetum pulvinatae* Nowak 1960. *Leproplaca cirrochroa* has high frequency in *Peccanio coralloidis-Thyreetum pulvinatae*; however, the species is diagnostic for *Caloplacetum cirrochroa* Poelt 1952 ex Breuer 1971, together with *Polyozosia hagenii* (Pers.) S.Y. Kondr., L. Lőkös et Farkas, *P. albescens* (Hoffm.) S.Y. Kondr., L. Lőkös et Farkas, *P. crenulata* S.Y. Kondr., L. Lőkös et Farkas, *Verrucaria muralis* Ach s. l., and *Candelariella aurella* (Hoffm.) Zahlbr. (see the synoptic table in Breuer, 1971). This association does not include

cyanobacterial lichens. It requires additional study and neotypification (Roux et al., 2009). Hence, the diagnostic species of *Peccanio coralloides-Thyreectum pulvinatae* are *Enchylium polycarpon* (Hoffm.) Otálora, P.M. Jørg. et Wedin, *Leproplaca cirrochroa*, *Placynthium nigrum*, *Placidium rufescens* (Ach.) Massal, *Toninia candida* (F. Weber) Th. Fr. and *Synalissa ramulosa* (Bernh.) Fr.

Seven relevés were named as *Thyrea nigritella-Anema moelingensis* comm. (Wirth, 1972). These communities cover wetter spots among conglomerates on the S exposed bank of the Rokytná River in the Czech Republic. Later, Wirth has corrected the species composition in the association. The species reported as *Anema moedlingense* Zahlbr. was redefined as *A. tumidulum*, and that was reflected in the community name "Gonohymenia nigritella-Anema tumidulum-Soc" (Wirth, 1995). Sterile *Porocyphus coccodes* Flot. ex Körb. was observed with high cover and frequency (Wirth, 1972). However, this species is very rare in the Czech Republic. It was only collected twice during the period from 1960 to 2010 (Vondrák et al., 2010). The locations from the Rokytná River have not been cited in that paper. The identity of *Porocyphus coccodes* is in need of checking both in herbarium specimens and in field. *Staurothele frustulenta* Vainio is another high frequency species in the *Thyrea nigritella-Anema moelingensis* comm. cluster; that species was absent in the relevés from Ukraine. However, the species was reported previously from the Dnister cliffs, but was not recorded in our relevés. Hence, we propose to validate *Thyrea nigritella-Anema moelingensis* comm. as a new association *Thallinocarpo nigritelli-Anemum tumidulae* (see below) within the alliance *Peccanion coralloidis*. Diagnostic species of the association should be *Thallinocarpon nigritellum*, *Anema tumidulum*, *Staurothele frustulenta*, and *Anema nodulosum*. According to Bültmann (2015), the alliance *Peccanion coralloidis* has 11 characteristic species (Bültmann et al., 2015), including *Anema decipiens*, *Psorotichia schaeereri*, and *Peccania coralloides*. Our studies have confirmed the diagnostic significance of these species for the mentioned alliance.

Two associations of *Peccanion coralloidis* differ by their ecological preferences. The type association *Peccanio coralloidis-Thyreectum pulvinatae* overgrows vertical exposed surfaces in water tracks in low elevations. The *Thallinocarpo nigritelli-Anemum tumidulae* occupy similar habitats, but are located in the xeric geolitoral zone along the river banks. The alliance *Peccanion coralloidis* and order *Collematetalia cristati* are reported from Ukraine for the first time here.

Syntaxonomy

Peccanio coralloidis-Thyreectum pulvinatae Nowak 1960

Lectotype, *hoc loco*: Nowak, 1960: table 16, relevé 2 [*Anema decipiens* (1.2), *Enchylium polycarpon* (1.3), *Lathagrium fuscovirens* (+), *Leproplaca cirrochroa* (1.2), *Peccania coralloides* (1.2), *Placidium rufescens* (1.2), *Psorotichia schaeereri* s. l. (1.2), *Pyrenodesmia chalybaea* (+), *Thyrea confusa* (3.2), *Toninia candida* (1.3), *Variospora velana* (+)]: Poland, Dolina Bętkowska, 280 m a.s.l., J. Novak, no date.

Diagnostic species: *Enchylium polycarpon*, *Leproplaca cirrochroa*, *Placidium rufescens*, *Placynthium nigrum*, *Toninia candida*, *Synalissa ramulosa*.

Thallinocarpo nigritelli-Anemum tumidulae (Wirth 1972), ass. nova, *hoc loco*

Holotype: Wirth, 1972, page 254, table 40, relevé 1 [*Anema tumidulum* (as *A. moedlingense*) (2b), *Circinaria hoffmanniana* (+), *Dermatocarpon miniatum* (+), ?*Porocyphus coccodes* (3), *Staurothele frustulenta* (як *Staurothele catalepta*) (2m), *Thallinocarpon nigritellum* (2b), *Thyrea confusa* (2m)]: Czech Republic, Moravia, Rokytná River, between Rokytná and Budkovice, NE from Moravský Krumlov, 260 m a.s.l., 49.0650 N, 16.3337 E, V. Wirth, no data.

Diagnostic species: *Anema tumidulum*, *Anema nodulosum*, *Thallinocarpon nigritellum*, *Staurothele frustulenta*, and *Porocyphus coccodes*.

Conclusions

Anema tumidulum, *A. nodulosum*, and *Pyrenocarpon thelostomum* are reported from the Dnister limestone cliffs (Ukraine) for the first time. A lectotype of the association *Peccanio coralloidis-Thyreectum pulvinatae* Nowak 1960 is proposed. The association *Thallinocarpo nigritelli-Anemum tumidulae* (Wirth 1972) is validated. These are rare associations known only from the Czech Republic and Ukraine up to now. The alliance *Peccanion coralloidis* and order *Collematetalia cristati* are reported from Ukraine for the first time.

Acknowledgements

We are grateful to Olesya Bezsmertna, Vasyl Budzhak, Illia Chorney, Olga Chusova, Yakiv Didukh, Oxana Kucher, Ivan Moysienko, Yulia Rozenblit, and Yulia Vashenyak for organization of

the excursion in the Dnister Canyon; Nadya Skobel' for providing the article of J. Nowak. We are grateful to the National Research Foundation of Ukraine for the support of the Project (No 2020.01/0140) within the framework of which we carried out our research, as well as to the Ukrainian Nature Conservation Group for financial support of the expedition costs. Alexander Khodosovtsev is grateful to researchers of the Center for Molecular Medicine (UMC Utrecht, The Netherlands), especially Prof. Saskia van Mil and Dr. Anna Mukha, for providing the microscope "Zeiss Axioscope" for the Kherson State University (Ukraine) that enabled his work in Kyiv while Kherson was temporarily occupied during the Russian invasion.

Перші знахідки лишайників *Anema nodulosum*, *A. tumidulum* і *Pyrenocarpon thelostomum* (*Lichenales*, *Lichinaceae*) в Україні та доповнення до класу *Collematetea cristati*

Реферат. Наведена інформація щодо поширення та екологічних уподобань нових для України видів лишайників *Anema tumidulum*, *A. nodulosum* та *Pyrenocarpon thelostomum*, які є елементами угруповання класу *Collematetea cristati*. Нові для України представники роду *Anema* зростали на експонованих прямовисніх вапнякових кіліфах південної та східної експозицій у місцях тимчасових водостоків (чорна зона), що синтаксономічно відносять до класу *Collematetea cristati*. Ці види формують угруповання з *Anema decipiens*, *Psorotrichia schaeereri*, *Peccania coralloides*, *Thallinocarpon nigrillum*, *Thyreocarpon confusa* та *Verrucaria nigrescens* s. l. Аналізований масив фітосоціологічних даних включав три описи з України, а також 14 описів з літературних джерел: сім описів асоціації *Peccania coralloidis*

Thyreectum pulvinatae Nowak 1960 з Польщі та сім описів угруповання *Thyrea nigrinella* – *Anema moelingensis* comm. з Чеської Республіки. Аналіз був проведений у програмі JUICE за допомогою кластерного аналізу. Аналізовані описи розділилися за двома кластерами. Три описи з вапнякових кліфів Дністровського каньйону опинилися в одному кластері з угрупованнями *Thyrea nigrinella* – *Anema moelingensis* comm. з Чеської Республіки. Ми розглядаємо такі угруповання як нову для науки асоціацію *Thallinocarpo nigrinelli-Anemum tumidulae* (Wirth 1972). Діагностичними видами її є *Thallinocarpon nigrinellum*, *Anema tumidulum*, *Staurothele frustulenta* та *Anema nodulosum*. Запропоновано лектотип асоціації *Peccanio coralloidis-Thyreectum pulvinatae* Nowak 1960. Діагностичні види асоціації *Enchylium polycarpon*, *Leproplaca cirrochroa*, *Placidium rufescens*, *Placynthium nigrum*, *Toninia candida*, *Synalissa symphorea*. Дві асоціації союзу *Peccanion coralloidis* відрізняються екологічними уподобаннями. Типова асоціація союзу *Peccanio coralloidis-Thyreectum pulvinatae* трапляється на прямовисніх експонованих вапнякових скелях на місцях тимчасових водостоків. Асоціація *Thallinocarpo nigrinelli-Anemum tumidulae* займає подібні біотопи, але які розташовані в зоні ксеричної геоліторалі рівнинних річок. Союз *Peccanion coralloidis* та порядок *Collematetalia cristati* вперше наводяться для України.

Ключові слова: вапняки, Дністровський каньйон, кліфи, лишайникові угруповання, синтаксономія, тимчасові водостоки, *Peccanion coralloidis*
